

Capital follows proof.

A Solana vault marketplace where traders earn allocation only after proving performance with their own first-loss capital.

Proof-gated vaults on Solana

Paper mode - first loss - public records

Managed DeFi vaults still run on trust.

Investors are asked to fund managers before seeing enough proof, while managers keep upside without enough downside.

- 01 No required skin in the game
- 02 No enforced track record before deposits
- 03 Manual unwinds create trust assumptions

PROOF OBJECT

Arcadia turns those social assumptions into protocol checks.

NO SKIN

NO PROOF

NO EXIT

Solana rails make proof-gated vaults practical.

Fast settlement, public program state, Pyth prices, and Jupiter routing let Arcadia enforce risk controls in the product loop.

- 01 Public records replace unverifiable claims
- 02 Fresh NAV makes withdrawals measurable
- 03 Routing support can unwind exposure when liquidity is short

PROOF OBJECT

No off-chain spreadsheet needs to decide whether an investor can exit.

A marketplace for traders who prove first.

Investors browse graduated vaults by buffer, performance, health, and strategy instead of trusting a pitch.

- 01 Compact vault discovery
- 02 Risk and buffer visible upfront
- 03 Portfolio and alerts built around withdrawal confidence

PROOF OBJECT

The marketplace is designed as the **first product surface, not a marketing page.**

The trader's money is the first fuse.

Junior capital protects senior investor capital and shrinks trading freedom as the buffer deteriorates.

- 01 Paper mode before investor access
- 02 First-loss junior buffer
- 03 Dynamic position limits as health falls

PROOF OBJECT

The manager UI shows progress, capital, status, and limits as operating constraints.

One flow, two roles, strict boundaries.

Arcadia separates investor discovery from trader operations so each role sees the right controls.

- 01 Landing to marketplace
- 02 Vault detail to deposit/withdrawal clarity
- 03 Manager console to trade limits and operations

PROOF OBJECT

Investor views do not expose execution controls; trader views focus on vault management.

Withdrawal safety is part of accounting, not support.

The v1 model uses USDC base liquidity and WSOL exposure so withdrawals can be valued and protected.

- 01 **Pyth-backed SOL/USDC NAV**
- 02 **10% liquid USDC reserve guard**
- 03 **Jupiter-assisted WSOL unwind design**

PROOF OBJECT

Shares were removed from the user model; investor data now tracks principal and claim.

Arcadia is stronger because it is on-chain.

The product relies on public state, non-custodial custody, composable vault records, and deterministic execution paths.

- 01 Managers cannot edit their past
- 02 Investors can verify state
- 03 Indexers can materialize public performance

PROOF OBJECT

The program, generated clients, frontend, and indexer are designed as one Solana-native loop.

The MVP is already a real product surface.

Arcadia has a polished frontend, role-gated flows, program design, indexer scaffold, and tests around core accounting behavior.

- 01 Arcadia UI and SVG brand system
- 02 USDC/WSOL accounting plan implemented in program direction
- 03 Frontend tests/build/lint passing before media work

PROOF OBJECT

The demo package captures the app **directly from localhost.**

Help Arcadia recruit the first serious managers.

Colosseum support helps move Arcadia from MVP to pilot vaults with disciplined traders and real feedback.

- 01 Select Arcadia for the Solana DeFi track
- 02 Introduce pilot traders and protocol reviewers
- 03 Pressure-test withdrawal safety before mainnet

PROOF OBJECT

The next milestone is not more hype.
It is guarded live capital with visible proof.
